

Overload of the third-level distribution box

Overview

Overloading occurs when the current demand exceeds the system's capacity, causing excessive heat and potentially damaging components. This may result from various factors, including increased load demand, outdated infrastructure, or improper system design. The three-level distribution system refers to a system that distributes electric power through three levels of distribution devices from the incoming power line at the construction site to the electrical equipment. The following is a detailed introduction about it: - **First-level Distribution. These can help you find an overloaded distribution board early. Keep your total electrical load under 80% of your main breaker's rating. This helps stop overheating and fire dangers. Each tier plays a distinct and non-negotiable role. In a newly constructed residential area, a 10kV power line is introduced into the substation. After stepping down the voltage through the transformer's low-voltage side (0.
